Inquiry: how does factorization in general (non-atomic) integral domains work? Abstract tactic: look at problem in some category, \mathbf{C} , through a functorial lens into (or out of) some better-known category, \mathbf{D} . Examples: Presheaves assign topological properties to \mathbf{C} , group representations place groups into \mathbf{C} , etc. Our setting: map integral domains into partially ordered abelian groups.

- (i) **Background:** po-groups, integral domains, factorization, sell you on the idea with the Jaffard-Kaplansky-Ohm Theorem
- (ii) **Main object:** We build the group of divisibility functor $\mathfrak{G} : \mathbf{Dom} \rightarrow \mathbf{Pog}$
- (iii) **Consequences:** JKO generalization, cochain complexes, their cohomology groups, what torsion means

Background I: What is the group of divisibility?

Integral domains always have a field of fractions:

$$D \subseteq \mathbb{F} = \left\{ \frac{y}{x} \mid x, y \in D, x \neq 0 \right\}$$

Divisibility in D provides a partial order on $\mathbb{F}^\times / U(D)$:

$$\frac{y}{x} \in D \cap \mathbb{F} \Leftrightarrow \bar{x} \leq \bar{y} \text{ in } \mathbb{F}^\times / U(D)$$

Example: In $\mathbb{Z} \subseteq \mathbb{Q}$, we have $\frac{1}{9} \leq \frac{2}{3}$ since $\frac{2/3}{1/9} = 6 \in \mathbb{Z}$.

Background II: Group of Div. Properties

This gives us a partially ordered abelian group

$G(D) = \mathbb{F}^\times / U(D)$ (po-group) with some nice properties:

(i) Positive elements are domain elements:

$$\bar{1} < \bar{\frac{x}{y}} \Rightarrow \frac{x}{y} \in D$$

(ii) Minimal positive/atoms: since $\bar{1} < \bar{y} \leq \bar{x}$ if and only if $y \in D$ and $y \mid x$ in D . . . irreducibles in D give atoms in $G(D)$.

(iii) Notion of convexity: $H \subseteq G, h_1 \leq g \leq h_2 \Rightarrow g \in H$

(iv) Maps between po-groups: given $G \rightarrow G/H, xH \preceq yH$ if and only if $x \leq yh$ for some $h \in H$ (reflexive, transitive, but not antisymmetric). Analogy: non-abelian setting, kernels are normal... in abelian po-groups, we will require kernels to be convex (first iso theorem!)

Theorem (First o-Isomorphism)

Let G_1, G_2 be (abelian) po-groups and $\phi : G_1 \rightarrow G_2$ a group homomorphism that is order-preserving ($x \leq y \Rightarrow \phi(x) \leq \phi(y)$). Then:

- (i) $\ker(\phi)$ is convex subgroup of G_1 from antisymmetry,
- (ii) $\phi(G_1)$ is a subgroup of G_2 , and
- (iii) o-isomorphism: $\phi(G_1) \simeq G_1 / \ker(\phi)$

Defs/Facts: A group homomorphism $f : G_1 \rightarrow G_2$ is an *o-homomorphism* if $x \leq y \Rightarrow f(x) \leq f(y)$. An o-hom, f , is called an *o-epimorphism* (o-epic) if $f : G \rightarrow G/H$ has convex H and $f(G^+) = (G/H)^+$. An o-epic f that is a group isomorphism is called an *o-isomorphism* (or an o-iso).

Po-groups are nice: factorization behavior in the domain is encoded in the partial order.

Theorem (Jaffard-Kaplansky-Ohm)

Any lattice-ordered group, G , is the group of divisibility of a Bézout domain, D .

Recall Bézout domains enjoy greatest common divisors that are linear combinations.

Background IV: JKO Proof Sketch (Ohm)

Assume G is lattice ordered. Then G admits a *lattice realization*: \exists o-iso $\delta : G \rightarrow \bigoplus_{\lambda \in \Lambda} G_\lambda$ where (i) $\delta(a \wedge b) = \delta(a) \wedge \delta(b)$, (ii) each $\pi_\lambda \circ \delta$ is surjective, (iii) each G_λ lattice ordered .

Build a polynomial field extension $K = \mathbb{F}(\{X_g \mid g \in G\})$ and valuation maps defined on monomials

$$\begin{aligned}\omega_\lambda : K &\rightarrow G_\lambda \\ X_g^n &\mapsto n \cdot \pi_\lambda \circ \delta(g)\end{aligned}$$

Extend to polynomials: $\omega_\lambda(f(\underline{X})) = \inf \omega_\lambda(m)$ (inf taken over monomials). Extend to rationals: $\omega_\lambda(f/g) = \omega_\lambda(f) - \omega_\lambda(g)$.

Then the following map may be regarded as a semivaluation:

$$\omega(f) = \delta^{-1} ((\omega_\lambda(f))_{\lambda \in \Lambda}) \in G$$

with domain $D = \{f \in K \mid \omega(f) \geq 0\}$. All that remains: D is an integral domain whose group of divisibility is o-iso to G , and it's Bézout... (omitted).

Factorization informs po-group behavior but also vice versa.

Question: given po-group G , can we find a domain, D , such that $G = G(D)$? In general, no, not all po-groups come from groups of divisibility.

Question (JKO Extension): given a po-group, G , can we find a domain, D , such that $G \approx G(D)$ in some sense?

Main Object I: Mott's Correspondence

For a functorial look, we need a functor, so we need categories. JL Mott proved the following theorem (1973):

Theorem (Mott)

Let D be an integral domain and $G(D)$ be its group of divisibility. Let

$$\mathcal{S} = \{S \subseteq D \mid 0 \notin S, S \text{ sat'd, mult. closed}\}$$

$$\mathcal{H} = \{H \subseteq G(D) \mid H \text{ convex directed subgp}\}$$

Then there is a one-to-one correspondence, say $\Theta : \mathcal{S} \rightarrow \mathcal{H}$. Furthermore, for any $S \in \mathcal{S}$, we have the equality $G(D_S) = G(D)/\Theta(S)$.

Since $\Theta(S)$ is convex, $G(D)/\Theta(S)$ is a po-group...

and B.
Goodell

Plan

Background

Main Object:
Functor

Consequences

Further
Routes

Main Object II: Group of Div. as a Functor

Define **Dom**, **Pog**, \mathfrak{G} like so:

- (i) Objects of **Dom**: integral domains, D . Arrows: (sat'd) localizations, $D \subseteq D_S$.
- (ii) Objects of **Pog**: abelian po-groups, G . Arrows: po-group o-homom. (convex kernels), $f : G_1 \rightarrow G_2$.
- (iii) Define $\mathfrak{G} : \mathbf{Dom} \rightarrow \mathbf{Pog}$ by defining $\mathfrak{G}(D) = G(D)$ and defining $\mathfrak{G}(D \subseteq D_S)$ to be $\pi : G(D) \rightarrow G(D)/\Theta(S)$.

Then \mathfrak{G} is a covariant functor and the following diagram commutes:

$$\begin{array}{ccc} D & \xrightarrow{\mathfrak{G}} & \mathfrak{G}(D) = G(D) \\ \downarrow \subseteq & & \downarrow \pi \\ D_S & \xrightarrow{\mathfrak{G}} & \mathfrak{G}(D_S) = G(D)/\Theta(S) \end{array}$$

Main Object III: Through the Functorial Looking Glass

A Functorial
Look at
Factorization

J. Coykendall
and B.
Goodell

Plan

Background

Main Object:
Functor

Consequences

Further
Routes

To formalize the JKO extension question, regard the group of divisibility as a functor, $\mathfrak{G} : \mathbf{Dom} \rightarrow \mathbf{Pog}$ as above.

Def: Given any functor $F : \mathbf{C} \rightarrow \mathbf{D}$, an *initial morphism* from $D \in \mathbf{D}$ to F is a pair, (C, ϕ) , which consists of an object $C \in \mathbf{C}$ and an arrow in \mathbf{D} with the universal mapping property:

$$\begin{array}{ccccc} C & \xrightarrow{F} & FC & \xleftarrow{\phi} & D \\ | & & | & & \swarrow f \\ g \downarrow & & Fg \downarrow & & \\ C' & \xrightarrow{F} & FC' & & \end{array}$$

In a sense, FC is the first functorial image D is allowed to touch.

Main Object IV: Toward the Functor

Hence, an *initial morphism* from any $H \in \mathbf{Pog}$ to \mathfrak{G} would be a pair, (D, ϕ) , which consists of a domain, $D \in \mathbf{Dom}$, and an arrow in \mathbf{Pog} , say ϕ , universal in the diagram

$$\begin{array}{ccccc} D & \xrightarrow{\mathfrak{G}} & \mathfrak{G}(D) = G(D) & \xleftarrow{\phi} & H \\ | & & | & \searrow f & \\ g \downarrow & & \mathfrak{G}(g) \downarrow & & \\ A & \xrightarrow{\mathfrak{G}} & \mathfrak{G}(A) = G(A) & & \end{array}$$

That is: $G(D)$ is the first group of divisibility that the arbitrary po-group H can touch. Here, $g : D \rightarrow A$ is a localization, $\mathfrak{G}(g) : G(D) \rightarrow G(A)$ is o-epic. We want to find a domain, D , such that for any $f : H \rightarrow G(A)$, we can fit $D \subseteq A$ with $A = D_S$ for some S . Tall order?

Recall: JKO Theorem establishes that lattice ordered abelian po-groups are groups of divisibility. The JKO extension question: for an arbitrary abelian po-group, G , does an initial morphism from G to \mathfrak{G} always exist?

Now we have our functor, so we may be able to start answering the question.

Consequences I: JKO extension probably false in general

A Functorial
Look at
Factorization

Routes

Lemma: If initial morphisms always exist to a functor, such as \mathcal{G} , then \mathcal{G} is a right-adjoint ($\exists \mathcal{D} : \mathbf{Pog} \rightarrow \mathbf{Dom}$ such that $\mathcal{D} \dashv \mathcal{G}$).

But this is almost surely too much to ask for on the unrestricted categories.

Certainly \mathcal{G} restricted to the categories of Bézout domains and lattice-ordered po-groups has an adjoint (corollary of the JKO theorem). JKO question starts to get pretty abstract: which subcategories of \mathbf{Dom} have initial morphisms to \mathcal{G} ? (No answers yet...)

Onto some concrete results from \mathcal{G} .

Consequences II: Towers of Localizations

A Functorial
Look at
Factorization

J. Coykendall
and B.
Goodell

Plan

Background

Main Object:
Functor

Consequences

Routes

What else can we do with the functor? Towers of localizations turn into projections

$$\begin{array}{ccccccc} D & \xrightarrow{\subseteq} & D_{S_1} & \xrightarrow{\subseteq} & D_{S_2} & \xrightarrow{\subseteq} & \dots \\ \downarrow \mathfrak{G} & & \downarrow \mathfrak{G} & & \downarrow \mathfrak{G} & & \\ G(D) & \xrightarrow{\pi_0} \twoheadrightarrow & G(D)/\Theta(S_1) & \xrightarrow{\pi_1} \twoheadrightarrow & G(D)/\Theta(S_2) & \xrightarrow{\pi_2} \twoheadrightarrow & \dots \end{array}$$

We can very generally convert (bottom) surjections into a multitude of cochain complexes by including kernels in the diagram and their inverse images... but...

Before applying the above, where are we localizing?

Ex: Let R be a 2-dimensional discrete valuation domain with prime spectrum $0 \subseteq \mathfrak{p} \subseteq \mathfrak{m} \subseteq R$.

- (i) The maximal ideal is principal, say $\mathfrak{m} = (x)$.
- (ii) The element x is a unique irreducible (up to units).
- (iii) Every nonzero nonunit factors into a power of x and another element.
- (iv) No element of \mathfrak{p} is a product of irreducibles.
- (v) Elements in $\mathfrak{m} \setminus \mathfrak{p}$ are atomic (products of x).
- (vi) Localizing at \mathfrak{p} yields a PID, localizing at 0 yields the quotient field.

Just weird! If we remove the non-atoms, we get a field, i.e. no factorization information. So we localize at atoms.

Consequences IV: Localizing at atoms

A Functorial
Look at
Factorization

J. Coykendall
and B.
Goodell

Plan

Background

Main Object:
Functor

Consequences

Further
Routes

If we localize at saturated multiplicatively closed subsets generated by irreducibles, we are projecting onto quotient groups with $\ker(\pi)$ convex, directed, generated by atoms.

So if A is the subgroup generated by atoms and $\ker(\pi)$ is the smallest convex subgroup containing A , then we get

$$G_0 \rightarrow G_1 = G_0 / \ker(\pi_0) \rightarrow G_2 = G_0 / \ker(\pi_1) \rightarrow \cdots$$

How to construct cochain complexes?

Consequences IV: Build cochain complexes

Further
Routes

We get the (exact) cochain complex

$$\hat{K}_\bullet = \hat{K}_0 \rightarrow \hat{K}_1 \rightarrow \dots$$

and the (trivial) complexes

$$\ker(\cdot)_\bullet = \ker(\pi_0) \rightarrow \ker(\pi_1) \rightarrow \dots$$

$$A_\bullet = A_0 \rightarrow A_1 \rightarrow \dots$$

And the generally nontrivial, nonexact

$$\hat{A}_\bullet = \hat{A}_0 \rightarrow \hat{A}_1 \rightarrow \dots$$

which has n^{th} cohomology group $\ker(\pi_n)/A_n$. *More structure in $\ker(\pi_n)$ gives more cochain complexes.*

Consequences VII: So what is torsion?

A Functorial
Look at
Factorization

J. Coykendall
and B.
Goodell

Plan

Background

Main Object:
Functor

Consequences

Further
Routes

Every $\ker(\pi_i)$ is the convex directed subgroup generated by atoms. Kernels contain $A_i \subseteq \ker(\pi_i)$ (directed subgroup generated atoms). This gives us the n^{th} cohomology group $\ker(\pi_n)/A_n$.

Mott's correspondence: $\ker(\pi) \subseteq G(D)$ corresponds to the saturated multiplicatively closed set generated by the irreducibles. **Similarly:** A_n corresponds to the multiplicatively closed set generated by the irreducibles, need not be saturated.

Consequently, *torsion* (group) elements of the cohomology correspond to *non-atomic divisors of atomic ring elements*: elements in the purgatory between atomic and antimatter.

(Some) Further Routes of Inquiry

- (i) Expanding Bézout domains to the largest subcategory of **Dom** that admits a left adjoint for \mathfrak{G} .
- (ii) Structure theorems, sequence of group projections.
- (iii) Examining the cohomological consequences of a more rich structure in the kernels.
- (iv) Groups of divisibility: intersection of partial orders and group theory. Can these techniques be meaningfully extended to other famous po-groups (algebraic K-theory, etc.)?
- (v) Factorization and topology: connections between partially ordered topological spaces and po-group theory, Haar measures.
- (vi) Orders and relations define graphs: graph-theoretic consequences for factorization? Factorization consequences for graph theory?
